BACKGROUND & AIMS: Helicobacter pylori infection induces an inflammatory response, which can contribute to gastric tumorigenesis. Induction of cyclooxygenase-2 (COX-2) results in production of prostaglandin E2 (PGE2), which mediates inflammation. We investigated the roles of bacterial infection and PGE2 signaling in gastric tumorigenesis in mice. METHODS: We generated a germfree (GF) colony of K19-Wnt1/C2mE mice (Gan mice); these mice develop gastric cancer. We examined tumor phenotypes, expression of cytokines and chemokines, and recruitment of macrophages. We also investigated PGE2 signaling through the PGE2 receptor subtype 4 (EP4) in Gan mice given specific inhibitors.

RESULTS: Gan mice raised in a specific pathogen-free facility developed large gastric tumors, whereas gastric tumorigenesis was significantly suppressed in GF-Gan mice; reconstitution of commensal flora or infection with Helicobacter felis induced gastric tumor development in these mice. Macrophage infiltration was significantly suppressed in the stomachs of GF-Gan mice. Gan mice given an EP4 inhibitor had decreased expression of cytokines and chemokines. PGE2 signaling and bacterial infection or stimulation with lipopolysaccharide induced expression of the chemokine C-C motif ligand 2 (CCL2) (which attracts macrophage) in tumor stromal cells or cultured macrophages, respectively. CCL2 inhibition suppressed macrophage infiltration in tumors, and depletion of macrophages from the tumors of Gan mice led to signs of tumor regression. Wnt signaling was suppressed in the tumors of GF-Gan and Gan mice given injections of tumor necrosis factor-α neutralizing antibody.

CONCLUSIONS: Bacterial infection and PGE2 signaling are required for gastric tumorigenesis in mice; they cooperate to up-regulate CCL2, which recruits macrophage to gastric tumors. Macrophage-derived tumor necrosis factor-α promotes Wnt signaling in epithelial cells, which contributes to gastric tumorigenesis.

Keywords: Stomach Cancer; Tumor Promotion; Bacterial Infection.

Gastric cancer is the second most common cause of cancer-related death in the world, and Helicobacter pylori infection is closely associated with gastric cancer development. Infections are estimated to be related to 15% of malignant cancer development, and infection-associated inflammation is a critical component of cancer development. For example, an inflammatory response promotes tumor cell proliferation, metastasis, and survival, whereas it suppresses antitumor immune responses. Moreover, the genetic polymorphisms in genes encoding inflammatory cytokines influence gastric tumorigenesis. These results suggest that an inflammatory cytokine network induced by H pylori infection plays a key role in gastric tumorigenesis.

Cyclooxygenase-2 (COX-2) is an inducible enzyme for prostaglandin biosynthesis, which plays an important role in both inflammation and tumorigenesis. Mouse model studies have indicated that induction of the COX-2/prostaglandin E2 (PGE2) pathway accelerates intestinal tumorigenesis through the induction of angiogenesis and suppression of apoptosis. Among 4 PGE2 receptors (EP1–EP4), EP4 receptor signaling has been shown to play an important role in intestinal tumorigenesis through the activation of epidermal growth factor receptor. The expression of COX-2 is also found in more than 70% of gastric cancers, which is suppressed by the eradication of H pylori, suggesting COX-2 induction by infection in the gastric mucosa. Transgenic mice expressing COX-2 and a PGE2 converting enzyme, microsomal prostaglandin E synthase-1 (mPGES-1), in the stomach develop hyperplasia with macrophage infiltration, indicating the role of PGE2 in macrophage recruitment. Tumor-associated macrophages (TAMs) play an important role in tumorigenesis through the enhancement of angiogenesis, migration, and remodeling. Moreover, the simultaneous activation of Wnt and the PGE2 pathways in the mouse stomach causes dysplastic tumor development.
development. Accordingly, it is possible that PGE2-dependent macrophage recruitment is one of the important mechanisms underlying the H pylori infection-associated inflammation in gastric tumorigenesis. However, the relationship between bacterial infection and PGE2 signaling in gastric tumorigenesis remains unclear.

Commensal bacteria constitutively stimulate the intestinal mucosa, inducing cytokines and chemokines at a basal level, which is important for homeostasis of the intestinal mucosa. The present study shows that indigenous bacteria constitutively stimulate the gastric mucosa, which is required for tumorigenesis in the Wnt-activated and PGE2-induced gastric mucosa. Bacterial colonization and PGE2 signaling through EP4 receptor cooperatively induced the expression of CCL2, which was a major pathway for macrophage recruitment in the gastric mucosa. Furthermore, depletion of macrophages caused regressive signs of tumors. These results indicate that bacterial infection and PGE2 signaling cooperatively recruit macrophages to the gastric mucosa, which promotes gastric cancer development.

Materials and Methods

Animal Experiments

The construction of K19-Wnt1 [Tg(Krt19-Wnt1)2Mao], K19-C2mE [Tg(Krt19-Ptgs2,Krt19-Ptges)8Tko], and K19-Wnt1/C2mE (Gan for Gastric neoplasia) [Tg(Krt19-Wnt1)2Mao/Tg(Krt19-Ptgs2,Krt19-Ptges)8Tko] transgenic mice was described previously (Supplementary Table 1). All mice used in the present study were backcrossed to C57BL/6 mice more than 12 times. Germfree (GF) mouse colonies of all genotypes and wild-type mice were established by cesarean derivation at the Central Institute for Experimental Animals (CIEA, Kawasaki, Japan), and the mice were raised in GF isolators under GF conditions. During the experiments, GF conditions were monitored by cultures of feces, bedding, and swabs in thioglycollate medium or potato dextrose broth every 2–5 weeks (Supplementary Table 2). Specific pathogen free (SPF)-raised mice were maintained in the SPF facility at Kanazawa University. The excluded pathogens in the SPF facility are listed in Supplementary Table 3. Mice were killed and examined at 30 and 55 weeks of age (n = 4 – 6 mice), and all experimental groups consisted of both female and male mice. Half of the glandular stomach was used for the histologic analysis, and the other half was used for RNA and protein sample preparation. Six GF Gan mice were moved to the SPF facility at 7 weeks of age, reconstituted with commensal flora by cohousing with SPF mice and adding dirty bedding from other cages and examined at 30 weeks of age. Helicobacter felis (ATCC 49179) were inoculated at 10^7/mouse PO to GF Gan mice at 30 weeks of age (n = 3 mice), and gastric phenotypes were examined at 55 weeks of age. The time course and experimental conditions for each group are shown in Supplementary Figure 1. All animal experiments were carried out according to the protocol approved by the Committee on Animal Experimentation of Kanazawa University.

Gastric pH Measurement

Gastric pH was measured as described. Briefly, mice were fasted overnight before necropsy. Sterile water (1.5 mL) was injected into the stomach, the stomach was massaged gently, and the pH of the gastric contents was measured using a pH meter.

Drug Treatment Experiments

The EP4 receptor inhibitor RQ-00015986/CJ-4279418 was provided from RaQualia Pharma Inc (Takeyo, Japan). Gan mice were treated with RQ-00015986 at 100 mg/kg/day PO from 27 or 52 weeks of age for 3 weeks (n = 4 or 5 mice). For inhibition of tumor necrosis factor (TNF)-α or CCL2, Gan mice were injected with a neutralizing antibody against TNF-α (AB-410-NA; R&D Systems, Minneapolis, MN) at 8 mg/kg/day intraperitoneally for 6 days (n = 3 mice) or an antibody against CCL2 (AF-479-NA; R&D Systems) at 1 mg/kg/day intraperitoneally for 3 days (n = 3 mice), respectively. Macrophages were depleted in vivo by injection of 200 µL clodronate (dichloromethylene bisphosphonate)-loaded liposomes intravenously every 3 days for 2 weeks as previously described. Clodronate was a gift from Roche Diagnostics GmbH (Mannheim, Germany) and was encapsulated in liposomes as described previously.

Histology and Immunobistochemistry

Stomach tissues were fixed in 4% paraformaldehyde, paraffin embedded, and sectioned at 4-µm thickness. These sections were stained with H&E or processed for immunostaining. Tissues were also embedded in OCT compound (Sakura Finetechical, Tokyo, Japan), frozen in liquid nitrogen, and sectioned at 10-µm thickness. The frozen sections were used for CCL2 immunostaining. Antibodies against the proton pump (MBL, Nagoya, Japan), F4/80 (Serotec, Oxford, UK), β-catenin (Sigma, St. Louis, MO), CCL2 (Hycult Biotech, Uden, The Netherlands), EP4 (MBL), CD44 (Millipore, Billerica, MA), EphB3 (Bioworld Technology, St. Louis Park, MN), and Ki-67 (Dako, Carpinteria, CA) were used as the primary antibodies. Staining signals were visualized using the Vectastain Elite Kit (Vector Laboratories, Burlingame, CA). For fluorescence immunostaining, Alexa Fluor 594 or Alexa Fluor 488 antibody (Molecular Probes, Eugene, OR) was used as the secondary antibody. Apoptosis was examined using the ApopTag Apoptosis Detection Kit (Millipore). The mean index for F4/80 (macrophage), proton pump (parietal cell), Ki-67, or apoptosis was calculated by counting labeled cells per microscopic field (200×) in 5 fields.
Scoring Tumor Volume and Preneoplastic Lesions

The mucosal thickness (tumor height) of the gastric tumors of Gan mice and the normal stomach of wild-type mice was measured from histology sections. The mucosal thickness relative to that of wild-type mice was calculated. The number of preneoplastic lesions in the whole glandular stomach of K19-Wnt1 mice was counted under a dissection microscope after staining with 0.05% toluidine blue. The histologic characteristics of gastric tumors and preneoplastic lesions were described previously.15 The histology of these lesions was confirmed after scoring.

Cell Culture Experiments

The RAW264 macrophage cells (RIKEN Bio-Resource Center, Tsukuba, Japan) were treated with lipopolysaccharide (LPS) (Sigma) for 24 hours at 1, 10, 50, 100, 1000, or 10,000 µg/mL with or without treatment with a COX-2 inhibitor, celecoxib, or RQ00015986 at 10 µmol/L, and the expression levels of CCL2 and cytokines were examined. Celecoxib was provided by Pfizer (New York, NY). For the primary culture of gastric epithelial cells, the glandular stomach of K19-Wnt1 mice was treated with 0.1% collagenase followed by trypsin, and epithelial cells were cultured in matrigel (BD Pharmingen, Franklin Lakes, NJ) with epidermal growth factor (EGF) (-) primary culture medium.13 The primary cultured cells were treated with RQ00015986 at 10 µmol/L for 6 days, and organoid structures consisting of epithelial cells larger than 0.2 mm in diameter were counted.

Immunoblotting Analysis

The tissues were homogenized and sonicated in lysis buffer. Thereafter, the specimens were centrifuged at 20,000g, and 10 µg of the supernatant protein sample was separated in 10% sodium dodecyl sulfate-polyacrylamide gel. An antibody against unphosphorylated active β-catenin (Millipore) was used as the primary antibody. Anti-β-actin (Sigma) was used as the internal control. The ECL detection system (GE Healthcare, Buckinghamshire, UK) was used to detect the signals.

Real-Time Reverse-Transcription Polymerase Chain Reaction

Tumor stroma and epithelial cell samples were separately collected from frozen sections using Laser Microdissection (Leica, Wetzlar, Germany). Total RNA was extracted from the tissues or microdissected samples using ISOGEN (Nippon Gene, Tokyo, Japan), reverse transcribed with PrimeScript RT reagent Kit (Takara, Tokyo, Japan), and polymerase chain reaction (PCR) amplified by Stratagene Mx300P (Agilent Technologies, Santa Clara, CA) using SYBR Premix ExTaqII (Takara). Primers for the real-time reverse-transcription polymerase chain reaction (RT-PCR) were purchased (Takara), and the primer sequences are shown in Supplementary Table 4.

Statistical Analysis

The data were analyzed using the unpaired t test and are presented as the means ± standard deviation. A value of P < .05 was considered to be statistically significant.

Results

Constitutive Stimulation of Gastric Mucosa by Indigenous Bacteria

To determine whether indigenous bacteria in the stomach stimulate the gastric mucosa, we examined the expression of cytokines and chemokines in the glandular stomach of germfree (GF) wild-type mice and control SPF mice by real-time RT-PCR (Figure 1A). Importantly, the expression levels of TNF-α, interleukin (IL)-1β, keratinocyte-derived chemokine (KC), and macrophage inflammatory protein-2 (MIP-2) decreased significantly in the GF mouse stomach compared with the SPF mice, whereas IL-6 expression slightly increased. These results indicate that commensal bacteria constitutively stimulate the gastric mucosa to induce inflammatory cytokines and chemokines at a basal level.

Gan mice were previously constructed by crossing K19-Wnt1 and K19-C2mE mice (Supplementary Table 1).13,15 We examined the number of parietal cells by immunostaining and measured intragastric pH in these models because bacterial growth is affected by intragastric acidity. The mean parietal cell index was similar in all strains, and the intragastric pH was around 3.5 (Figure 1B–D). However, in the dysplastic tumors of Gan mice, the number of parietal cells decreased significantly, and intragastric pH increased at 50–55 weeks of age. These results indicate that gastric acidity is not changed in Gan mice at early stages of disease compared with other models until large tumors develop at the later stages.

Suppression of Gastric Tumorigenesis in GF Mice

Gan mice raised in an SPF facility (SPF-Gan) developed large gastric tumors by 55 weeks of age (Figure 2A and B), and the mean tumor height increased to approximately 1.5-fold when compared with that at 30 weeks of age. In contrast, gastric tumorigenesis was significantly suppressed in the GF Gan (GF-Gan) mice, and the mean mucosal thickness of GF-Gan mice was less than 40% of the age-matched SPF-Gan mice (Figure 2A and B, Supplementary Figure 2). Approximately 40% of the SPF-Gan mice showed a moribund phenotype and thus were killed by 60 weeks of age, whereas all GF-Gan mice survived by 55 weeks of age (Figure 2C). Importantly, reconstitution of commensal bacteria in GF-Gan mice resulted in development of gastric tumors that were significantly larger than those of GF-Gan mice (Figure 2A, Supplementary Figure 2), and treatment of SPF-Gan mice with antibiotics significantly suppressed gastric tu-
mor growth (Supplementary Figure 3). These results indicate that colonization of indigenous bacteria is required for gastric tumor development. Moreover, infection with Helicobacter felis, separate species of Helicobacter pylori, in the GF-Gan mouse stomach at 30 weeks of age (GF-Gan/H felis mice) induced the development of gastric tumors by 55 weeks of age (Figure 2A and B). The infection of H felis in gastric glands was confirmed by microscopy of histology sections (Supplementary Figure 4). These results also indicate the role of infection in gastric tumorigenesis.

Apoptotic cells were found only on the mucosal surface of gastric tumors (Figure 2D), and the mean apoptosis index was 42.4% and 40.0% on the mucosal surface in SPF-Gan and GF-Gan mice, respectively. On the other hand, the number of Ki-67-labeled proliferating cells was significantly lower in the GF-Gan mouse stomach (Figure 2E and F), suggesting that bacterial colonization contributes to the tumor cell proliferation.

**Suppression of Gastric Tumorigenesis by Inhibition of the PGE2 Receptor EP4**

There are 4 PGE2 receptors (EP1—EP4), and the expression level of EP4 was increased significantly in Gan mouse tumors. SPF-Gan mice were thus treated with a specific EP4 inhibitor, RQ-00015986, for 3 weeks from 52

weeks of age (Supplementary Figure 1). Notably, gastric tumors regressed significantly following inhibition of EP4, and the mean tumor size decreased to 23% of that of the age-matched SPF-Gan mice (Figure 2A and B). Moreover, treatment of SPF-Gan mice with an EP4 inhibitor during the early stage of tumorigenesis from 27 weeks of age also suppressed tumor development significantly. These results indicate that EP4 signaling plays an important role in gastric tumorigenesis.

Bacterial Infection and EP4 Signaling for Inflammatory Responses

Submucosal lymphocyte infiltration was found in the SPF-Gan and GF->H felis mouse tumors but not in GF-Gan and EP4 inhibitor-treated Gan (EP4i-Gan) mice (Figure 3A), suggesting that both bacterial infection or colonization and EP4 signaling are required for inflammatory responses. Moreover, the expression level of proinflammatory cytokines, TNF-α, IL-1β, and IL-6 and chemokines, KC and MIP-2, were significantly elevated in the SPF-Gan and GF->H felis gastric tumors (Figure 3B), indicating inflammatory responses in the stomachs of these mice. In contrast, the expression of these cytokines and chemokines was not induced in the GF-Gan and EP4i-Gan mouse stomachs. The transgenic expression of COX-2 (Ptgs2) in the stomach was confirmed in all mouse groups except the wild-type mice, indicating that the PGE2 level was elevated in all groups of Gan mice. These results indicate that both infection and EP4 signaling are required for inflammatory responses in the stomach.

The expression of proinflammatory cytokines was predominantly detected in stromal cells when compared with tumor epithelial cells in SPF-Gan tumors (Figure 3C), suggesting that stromal macrophages were the major source of these cytokines. We thus examined macrophage infiltration by immunostaining. As expected, numerous macrophages were found in the SPF-Gan and GF->H felis Gan mouse tumors, whereas macrophage infiltration was suppressed in the GF-Gan and EP4i-Gan mice (Figure 3D). The number of macrophages in the GF-Gan and EP4i-Gan mouse stomachs decreased significantly to 11% and 33% of the SPF-Gan mouse level, respectively (Figure 3E). These results suggest that cooperation of bacterial infection or colonization with EP4 signaling contributes to macrophage recruitment to the gastric mucosa.

To examine the role of macrophages in gastric tumorigenesis, SPF-Gan mice were treated with clodronate liposomes to deplete macrophages in vivo. Macrophage-depleted areas were found by immunostaining in the clodronate liposome-injected Gan mouse tumors (Figure 3F). In the macrophage-depleted area, tumors showed regressive signs with atrophic changes of tumor cells or peel-off of tumor epithelial cells from the mucosal surface, suggesting that macrophages are important for the maintenance or survival of tumor epithelial cells.

Induction of CCL2 by Bacterial Infection and EP4 Signaling

The expression level of macrophage-tropic chemokines was examined in the SPF-K19-C2mE and GF-K19-C2mE mouse stomach. The PGE2 pathway but not Wnt signaling is activated in the glandular stomach of K19-C2mE mice (Supplementary Table 1). Importantly, expression of CCL2 and CCL8 increased significantly in the SPF-K19-C2mE mouse stomach compared with that in the wild-type mice (Figure 4A). In contrast, expression of CCL2 and CCL8 was not induced in the GF-K19-C2mE mouse stomach. Induction of CCL2 and CCL8 expression was also found in gastric tumors of SPF-Gan mice but not in GF-Gan mice (Figure 4B). These results suggest that PGE2 signaling and bacterial colonization cooperatively induce expression of CCL2 and CCL8 in the gastric mucosa.

Because CCL2 is an important chemokine for macrophage infiltration in colon tumors, we further examined CCL2 expression. CCL2-expressing cells were detected by immunostaining in the stroma of SPF-Gan mouse tumors where macrophages were accumulated (Figure 4C), suggesting that macrophages express CCL2. The stimulation of RAW264 macrophage cells with LPS induced the expression of CCL2 in a dose-dependent manner (Figure 4D). A low concentration of LPS was used for further experiments to examine the effect of low counts of indigenous bacterial colonization in the stomach. Importantly, treatment of RAW264 macrophages with an EP4 inhibitor significantly suppressed LPS-induced CCL2 expression (Figure 4E), suggesting that both EP4 signaling and LPS stimulation are required for CCL2 induction in macrophages.

To examine the role of CCL2 in macrophage recruitment in gastric tumors, SPF-Gan mice were treated with an anti-CCL2 neutralizing antibody. Notably, inhibition of CCL2 suppressed macrophage infiltration in tumors, although a few macrophages were still detected (Figure 4F), suggesting that CCL2 is a major chemokine that recruits macrophages to gastric tumors. In the macrophage-depleted tumor areas caused by CCL2 inhibition, tumors showed regressive signs, which was similar to the observations in the clodronate liposome-treated Gan mice (Figure 3F).

M2 Type Polarization of Macrophages in Gastric Tumors

TAMs play a pivotal role in tumor development. Macrophage activation is classified as “classically” activated (M1) or “alternatively” activated (M2) type, and TAMs generally express characteristics of M2-polarized macrophages. Interestingly, the expression of M2 macrophage markers, Ym1, Ym2, arginase 1 (Arg1), and transforming growth factor-β, increased significantly in both the SPF-K19-C2mE stomach and SPF-Gan tumors (Supplementary Figure 5A). Consistently, expression of
an M2 marker, mannose receptor, was detected by immunohistochemistry in the SPF-Gan mouse tumors (Supplementary Figure 5B). It has been reported that CD4<sup>+</sup>/H<sup>11001</sup>T cells regulate the M2 properties of macrophages. CD4<sup>+</sup> T cells infiltrated into the SPF-Gan mouse tumors (Supplementary Figure 5C). However, M2 macrophages were also found in SPF-Rag2<sup>−/−</sup>/H<sup>11002</sup>/H<sup>11002</sup>K19-C2mE mouse stomachs (Supplementary Figure 5D), suggesting...

(F) Immunostaining for F4/80 (red, arrowheads) and β-catenin (green) with DAPI staining (blue) in tumors of control SPF-Gan (left) and CCL2 antibody-treated SPF-Gan mice (right). Scale bars, 100 μm. Arrows in right panel indicate regressed tumors in the macrophage-depleted area.
that macrophages in the PGE2-induced inflammation can be polarized to the M2 type in the absence of T cells.

**EP4 Signaling on Macrophages and Epithelial Cells**

Expression of the EP4 receptor was detected by immunostaining in both tumor epithelial cells and stromal cells of SPF- and GF-Gan mice, whereas it was rarely detected in the GF-Gan or wild-type mouse stomach (Figure 5A). Induction of EP4 in SPF-Gan tumors was confirmed by real-time RT-PCR (Figure 5B). When RAW264 macrophages were stimulated with LPS, expression of COX-2 and mPGES-1, as well as proinflammatory cytokines, was elevated (Figure 5C). Importantly, treatment of LPS-stimulated macrophages with an EP4 inhibitor or celecoxib suppressed the induction of COX-2, IL-1\(\beta\), and IL-6. Moreover, inhibition of EP4 suppressed proliferation of the primary cultured gastric epithelial cells in matrigel (Figure 5D). These results suggest that EP4 signaling is also important for macrophage activation and epithelial cell proliferation.

**Wnt Promotion by Bacterial Infection and TNF-\(\alpha\) Stimulation**

Expression of Wnt-target genes, CD44 and Eph receptor B3 (EphB3), was significantly down-regulated in the GF-Gan and EP4i-Gan mouse stomachs (Figure 6A). In the wild-type mouse stomach, expression of CD44 was found only in the neck of the gastric gland, whereas EphB3 was not detected (Figure 6B). Notably, expression of CD44 and EphB3 was significantly induced in tumor epithelial cells of SPF-Gan mice, which was suppressed in GF-Gan mouse gastric tumors compared with SPF mice (Figure 6C), indicating that Wnt signaling activity is suppressed under GF conditions. We previously showed that macrophage-derived TNF-\(\alpha\) promotes Wnt signaling in gastric.
cancer cells. It is therefore possible that the decreased level of TNF-α in the GF-Gan and EP4i-Gan mouse stomachs resulted in suppression of Wnt signaling.

*K19-Wnt1* mice develop preneoplastic lesions caused by promotion of Wnt signaling by macrophage-derived TNF-α (Supplementary Table 1). Importantly, the number of preneoplastic lesions decreased significantly in the GF-K19-Wnt1 mice compared with the SPF-K19-Wnt1 mice (Figure 6D), suggesting that bacterial colonization is important for macrophage recruitment, which triggers TNF-α-induced Wnt promotion.

We next investigated whether TNF-α promotes Wnt signaling in the gastric tumor tissues. Treatment of the SPF-Gan mice with an anti-TNF-α neutralizing antibody resulted in down-regulation of TNF-α in tumors, possibly caused by suppression of macrophage activation (Figure 6E). Importantly, expression of EphB3, a Wnt-target gene, was also down-regulated. Consistently, the active β-catenin level decreased in gastric tumors by TNF-α inhibition (Figure 6F). These results indicate that macrophage-derived TNF-α enhances Wnt activity in gastric tumors, which may promote gastric tumorigenesis.

**Discussion**

Accumulating evidence has indicated that infection-associated inflammation plays an important role in cancer development. Bacterial infection stimulates toll-like receptors, which induces activation of the nuclear factor-κB (NF-κB) pathway. The activation of NF-κB causes tumor promotion through induction of growth factors and suppression of apoptosis. NF-κB activation
also induces COX-2 expression, which is followed by induction of the PGE2 pathway. The COX-2/PGE2 pathway plays a key role in intestinal tumorigenesis.\textsuperscript{5,9} These results indicate that infection plays a key role in the activation of the NF-\kappaB and PGE2 pathways, which promotes tumorigenesis. In the present study, we infected \textit{H felis} at 30 weeks of age to examine the effect of infection in tumorigenesis because we found a significant suppression of tumorigenesis in GF-Gan stomach at 30 weeks of age. Importantly, \textit{H felis} infection in GF-Gan mice induced gastric tumor development by 55 weeks. Accordingly, the present study indicates that bacterial infection is still required for tumorigenesis even after the induction of the PGE2 pathway.

It has been shown that PGE2 signaling through EP4 receptor is important for intestinal tumorigenesis through the activation of epidermal growth factor receptor.\textsuperscript{8} The current results also showed EP4 to play an important role in tumorigenesis. Bacterial colonization and EP4 signaling cooperatively induce expression of macrophage-tropic chemokine CCL2. It has been shown that CCL2 signaling is important for macrophage infiltration in colon cancers in the intestinal tumorigenesis.\textsuperscript{22} Accordingly, it is possible that expression of CCL2 induced by bacterial colonization and EP4 signaling is important for macrophage recruitment in gastric tumorigenesis.

Intestinal commensal bacteria stimulate the toll-like receptors in the mucosa, which is important for the proliferation of undifferentiated epithelial cells.\textsuperscript{16} Moreover, macrophages are an important niche component for the proliferation of intestinal progenitor cells in the tissue repair process.\textsuperscript{27} Accordingly, it is possible that the innate immune response to commensal bacteria is important for the proliferation of tumor epithelial cells through macrophage recruitment. On the other hand, acquired immunity by T cells is essential for \textit{H felis}-associated gastric pathology.\textsuperscript{28} It is thus possible that T cells play a role in gastric tumorigenesis in \textit{H felis}-infected GF-Gan mice. However, hyperplasia still developed, and the macrophages were polarized to M2, in the SPF-Rag2\textsuperscript{2/2} K19-CZmE mouse stomach (Supplementary Figure 5D), suggesting that increased PGE2 levels and commensal flora can trigger these gastric phenotypes without T-cell response.

We previously showed that macrophage-derived TNF-\(\alpha\) promotes Wnt signaling activity in gastric cancer cells, which contributes to gastric tumorigenesis.\textsuperscript{25} Moreover, Wnt activation levels correlate with the incidence of intestinal tumorigenesis in \textit{Apc} knockout mice,\textsuperscript{30} and promotion of Wnt signaling activity may play an important role in malignant progression.\textsuperscript{31} In the present study, inhibition of TNF-\(\alpha\) resulted in a decrease in Wnt signaling activity in gastric tumors, confirming that TNF-\(\alpha\) functions as a Wnt promoting factor in vivo. Notably, Wnt activity in the gastric tumors of GF-Gan mice was lower than that of SPF-Gan mice, which may have been caused by a decreased level of macrophage-derived TNF-\(\alpha\). Accordingly, it is possible that TNF-\(\alpha\)-dependent Wnt promotion is one of the important mechanisms by which macrophages induce tumorigenesis, which is triggered by bacterial colonization and EP4 signaling.

The COX-2/PGE2 pathway has been shown to suppress the T helper 1 immune response in the \textit{H pylori}-infected stomach.\textsuperscript{32} Notably, nonsteroidal anti-inflammatory drug treatment suppresses gastric carcinogenesis in the insulin-gastrin transgenic (INS-GAS) gastric tumor model mice. However, nonsteroidal anti-inflammatory drug treatment enhances gastritis in \textit{Helicobacter}-infected INS-GAS mice, which may promote gastric tumorigenesis. It is therefore possible that the role of PGE2 for immune responses and tumorigenesis varies according to the level of infection status, such as exogenous aggressive infection by \textit{Helicobacter} or commensal colonization, although this remains to be investigated.

In conclusion, bacterial infection or colonization, in cooperation with PGE2 signaling through the EP4 receptor, induces expression of CCL2, resulting in macrophage recruitment to gastric mucosa. TNF-\(\alpha\) produced by macrophages promotes Wnt signaling in the tumor cells, which may promote gastric tumorigenesis. Accordingly, the eradication and inhibition of the PGE2 pathway may be an effective strategy for preventing gastric cancer development.

Supplementary Materials and Methods

Depletion of Indigenous Bacteria

To deplete indigenous bacteria in the stomach, specific pathogen free (SPF)-Gan (Gan for Gastric neoplasia) mice (n = 5) were administered ampicillin (1 g/L; Sigma, St. Louis, MO), vancomycin (500 mg/L; Sigma), neomycin sulfate (1 g/L; Sigma), and metronidazole (1g/L; Sigma) in drinking water as previously described.1 Gastric tumors were examined by x-ray computerized tomography using a LaTheta LCT-100 instrument (Aloka, Tokyo, Japan) after 0, 2, and 4 weeks of antibiotic administration. The mean tumor area was calculated from computerized tomography images using a National Institute of Health (NIH) Image J software program (Bethesda, MD).

Histology and Immunohistochemistry

Stomach tissue specimens were fixed in 4% paraformaldehyde, paraffin-embedded, and sectioned at 4-μm thickness. Frozen sections were used for CD4 immunostaining. The construction of SPF-Rag2−/− K19-C2mE mice was described previously.2 Antibodies for β-catenin (Sigma), mannose receptor (AbD Serotec, Raleigh, NC), CD3ε (Santa Cruz Biotechnology, Santa Cruz, CA), and CD4 (BD Pharmingen, Columbus, NE) were used as the primary antibodies. Alexa Fluor 594 or Alexa Fluor 488 antibody (Molecular Probes, Eugene, OR) was used as the secondary antibody. Infection of Helicobacter felis in the gastric glands was confirmed using hematoxylin-stained paraffin sections of the H felis-infected germfree-Gan mouse stomach at X1000 magnification.

Expression Analysis of M2 Macrophage Markers

The expression profiles of M2 macrophage markers Ym1, Ym2, arginase 1 (Arg1), and transforming growth factor-β1 in Gan, K19-C2mE, and wild-type mouse stomachs were downloaded from the National Center for Biotechnology Information Gene Expression Omnibus (GEO; accession number GSE16902). These expression data were transformed to log10 ratios to the average of wild-type mouse samples.

RT, room temperature; Temp, temperature.

\(^a\)Thioglycollate medium.
\(^b\)Potato dextrose broth.
\(^c\)Samples were incubated in TGC at 37°C or at room temperature or in PDB at room temperature.

### Supplementary Table 3. List of Excluded Pathogens in Animal Room 4 of SPF Facility, Kanazawa University

- *Bordetella bronchiseptica*
- *Citrobacter rodentium*
- *Corynebacterium kutscheri*
- *Mycoplasma pulmonis*
- *Pasteurella pneumotropica*
- *Salmonella spp*
- *Streptococcus pneumoniae*
- *Pseudomonas aeruginosa*
- *Helicobacter hepaticus*
- *Clostridium piliforme*
- Ectromelia virus
- Sialodacryoadenitis virus (SDAV)
- Hanta virus
- Lymphocytic choriomeningitis virus (LCMV)
- Mouse hepatitis virus
- Sendai virus
- Intestinal protozoas (*Giardia muris, Spiroeches muris, Trichomonas muris, Octomitus pulcher, Coccidiosis*)
- Helminths (*Aspiculuris tetrapera, Syphacia obvelata*)
- Parasites (*Myobia sp, Polyplax serrata*)

**NOTE.** All SPF mice used in the present study were raised in this SPF room.

SPF, specific antigen free.

</table>

COX-2, cyclooxygenase-2; IL-1β, interleukin-1β; IL-6, interleukin-6; mPGES-1, microsomal prostaglandin E synthase-1; RT-PCR, reverse-transcription polymerase chain reaction; TNF-α, tumor necrosis factor-α; KC, keratinocyte-derived chemokine; MIP-2, macrophage inflammatory protein-2; CXCL, chemokine (C-X-C motif) ligand; CCL, chemokine (C-C motif) ligand; EP4, PGE2 receptor subtype 4; EphB3, Eph receptor B3.

### Supplementary Figure 2. Representative photographs of gastric tumor phenotypes at 30 weeks of age.

Wild-type mouse stomach, gastric tumors of SPF-Gan mouse, GF-Gan mouse, and GF-Gan mouse reconstituted with commensal bacteria (GF->SPF) are shown (from left to right). Arrowheads indicate gastric tumors in SPF-Gan, GF-Gan, and GF->SPF Gan mice.
Supplementary Figure 3. Suppression of gastric tumor growth by antibiotic treatment. (A) The mean tumor volumes calculated from x-ray computerized tomography (CT) images of control Gan mice (blue bars, left) and antibiotics-treated Gan mice (green bars, right) relative to the level at 0 weeks of treatment (closed bars) (mean ± standard deviation). *P < 0.05. (B) Representative x-ray CT images of gastric tumors of the same mice from the antibiotics-treated group (top) and control group (bottom) at 0 and 4 weeks of antibiotic treatment. The dashed lines indicate gastric tumors. Note that tumor growth was suppressed by treatment with antibiotics (top).
Supplementary Figure 4. Infection of *Helicobacter felis* in the lumen of the *H. felis*-infected GF-Gan mouse gastric glands (A and B). Arrowheads indicate *H. felis*. Scale bars, 50 μm. Original magnification, ×1000.
Supplementary Figure 5. M2 macrophages in Gan and K19-C2mE mouse stomachs. (A) The relative expression level of M2 macrophage markers—Ym1, Ym2, arginase 1 (Arg1), and transforming growth factor (TGF)-β1—in the K19-C2mE mouse stomach (blue) and Gan mouse tumors (red) in comparison with that in the wild-type mouse stomach (black) (mean log10 ratio with standard deviation). *P < .05 vs wild-type level. (B) Immunostaining of M2 macrophage marker, mannose receptor (green) and β-catenin (red) with 4',6-diamidino-2-phenylindole (DAPI) nuclear staining (blue) in Gan mouse tumors (left) and wild-type mouse stomach (right). (C) Immunostaining of CD3ε (left, red, arrowheads) or CD4 (right, red, arrowheads) and β-catenin (green) with DAPI staining (blue) of SPF-Gan mouse tumors. (D) Immunostaining of F4/80 (left, red, arrowheads) or mannose receptor (right, red, arrowheads) and β-catenin (green) with DAPI staining (blue) of the SPF-Rag2−/− K19-C2mE mouse stomach. Note that mannose receptor-expressing M2 macrophages were found in the T cell-depleted Rag2−/− K19-C2mE mouse inflamed stomach. Scale bars in B–D, 100 μm.
